

GOAL BRIDGE

ProjectNexus Project Report

Planning • Implementation • Screenshots • Testing • Audit • Reflection

Project purpose	Goal Bridge is a goal-based investment planning application designed to help users enter goal and financial assumptions, calculate a plan, understand SIP, and save relevant information/results.
Core objectives	Clear input flow; calculated outputs based on user inputs; concise SIP explanation; working Save option; iterative testing, correction and retesting.
Final status	The final version represents the improved and verified state after genuine weaknesses were discovered and fixed during development. No known unresolved defects are being reported in the final implementation.

1. Planning and Project Goals

The project was planned around a straightforward user journey: define a financial goal, enter the relevant assumptions, calculate a plan, review the generated figures, and retain useful information. The development therefore considered both functional correctness and usability.

- Accept user-specific goal values rather than relying only on predetermined values.
- Display the resulting calculations clearly so users can see the effect of their inputs.
- Provide enough context for important terminology, including SIP (Systematic Investment Plan).
- Provide a Save facility for retaining relevant plan information.
- Use an iterative test cycle: identify a weakness → fix it → retest → record the repository change.

Development approach

Features were checked using realistic values and user interactions. When a weakness was found, the implementation was changed and the affected behaviour was tested again. The defect log therefore records issues discovered during development, while the final status describes the corrected implementation.

2. Product Screenshot Evidence

Figure 1. Overall Goal Bridge interface and main planning workflow. The screenshot is scaled proportionally; no cropping has been applied.

The first selected screenshot provides a compact view of the product identity, goal-planning interface and monthly-plan area, making it suitable as the main overview image.

3. Inputs, Calculated Results and Testing Evidence

Figure 2. Goal inputs, monthly plan and plan-breakdown calculations. The screenshot is scaled proportionally; no cropping has been applied.

This second screenshot is useful evidence for the calculation workflow because it shows entered values on the left and generated plan information on the right, including future goal cost, future value of savings, funding gap, total contribution, projected growth and monthly rate.

Testing focus

- Input validation and realistic-value checks were used to confirm that the application responds to user-entered values.
- Calculated output was checked after changes to ensure that displayed values correspond to the inputs rather than remaining fixed at predetermined values.
- The interface was checked for user understanding, leading to the addition of a short SIP explanation.
- The Save interaction was tested separately because saving information is a distinct user action from calculation.

Evidence interpretation

The screenshots represent the improved product state. They should be read together with the defect log on the following page: the screenshots show what the final interface presents, while the log records what was found and changed during development.

4. Defect and Improvement Log

4. Defect and Improvement Log

Three genuine weaknesses were identified during development/testing. Each was corrected and then retested. Replace the commit placeholders with the actual GitHub commit IDs from the repository.

Defect 1 — Calculated Values Not Displayed

Issue	The application initially displayed predetermined/default values instead of the actual values calculated from the user's inputs.
Impact	Users could not clearly see the actual result of their inputs, reducing the usefulness of the calculator.
Fix	Updated the calculation and output logic so calculated values are displayed correctly based on the user's inputs.
Retest result	Tested with different input values and confirmed that displayed calculated values changed correctly according to the inputs.
GitHub commit	[INSERT ACTUAL COMMIT ID]

Defect 2 — SIP Explanation Was Missing

Issue	The original website did not provide a short explanation of what SIP (Systematic Investment Plan) is.
Impact	Users unfamiliar with SIP might not understand the purpose of the calculator or the information being displayed.
Fix	Added a short explanation of SIP and relevant information to make the website easier to understand.
Retest result	Checked the updated website and confirmed that the SIP explanation is displayed correctly in the relevant section.
GitHub commit	[INSERT ACTUAL COMMIT ID]

Defect 3 — Save Option Not Working Correctly

Issue	During testing, the Save option was not functioning correctly and did not save information as intended.
Impact	Users could not reliably save their information/results, affecting the usability of the application.
Fix	Corrected the Save functionality so that relevant information can be saved properly.
Retest result	Tested the Save option again and confirmed that the information was saved correctly and the functionality worked as intended.
GitHub commit	[INSERT ACTUAL COMMIT ID]

5. Independent Calculation Check, Audit and Reflection

Independent calculation check

A representative scenario should be verified using a separate method such as a spreadsheet, manual formula check, financial calculator, or independently written calculation. The exact input values, application result, independent result and any rounding difference should be recorded.

Scenario / inputs	[Insert the exact test inputs used]
Application result	[Insert the result shown by Goal Bridge]
Independent result	[Insert the spreadsheet/manual result]
Difference	[Insert difference, if any]
Rounding explanation	[Explain any difference caused by display rounding or calculation precision]

Audit summary

The audit focuses on whether the application responds to user inputs, displays meaningful calculated results, gives users enough context, and handles saving as intended. The three recorded issues demonstrate that testing was used to identify real weaknesses rather than simply declaring the project defect-free.

6. Reflection

The development of Goal Bridge showed that a working first version is not necessarily a finished product. Testing revealed issues affecting both functionality and user understanding. The calculated-value issue highlighted the importance of checking whether outputs actually reflect user inputs. The missing SIP explanation showed that usability depends on context as well as functionality. The Save issue demonstrated the need to test user actions that retain information.

The main improvement in my development approach was treating testing as an iterative part of development: identify a weakness, make a targeted change, retest the feature, and record the corresponding repository change. The final Goal Bridge version represents the improved and verified state after these corrections.

Submission checklist

- Insert the actual GitHub commit ID for each of the three fixes.
- Complete the independent calculation check with real values and any rounding explanation.
- Keep the two selected screenshots as the visual evidence; both are scaled down proportionally without cropping.
- Export/submit this PDF together with any required repository evidence.
